chd.hack. Q: When using

static_cast between types of

polymorphic lists, do I need

to explicitly make sure the

types are not const? The

standard says: A static_cast

can only convert to another

polymorphic list (or array) if

it can be guaranteed that the

original polymorphic list (or

array) was not const.

Otherwise, the behavior is undefined. To illustrate this, consider the following code:

```
struct A { static int foo(); };
struct B : public A { static int
foo(); }; struct C { static int
foo(); }; struct D : public B,
public C { static int foo(); };
int A::foo() { return 0; } int
    B::foo() { return 1; } int
    C::foo() { return 2; } int
    D::foo() { return 3; } Now I
can do this with static_cast,
like so: static_cast(A::foo())
static_cast(D::foo()) In the
second case I do: static_cast
```

from A^* to D^* `static_cast`
from B^* to D^* because that is
what `static_cast(A*)` refers to
`static_cast` from `const D*` to
 D^* Therefore when I do the
second case I must explicitly
make sure that the original
`const B*` is not the same as
 D^* , and when I do the third
case I must ensure that the
original `const D*` is not the
same as `const D*`. My
question is, is this always
necessary? Why? A: This is
an example of why
`static_cast(A::foo())` is

undefined behavior. You're casting a const pointer to B, so you can't change the pointer, but you're casting a pointer to a base of D, which means you can change its base class. It's undefined behavior. With `static_cast(A::foo())` the static cast succeeds, the pointer is changed to point to a base of D, and you can, in theory 6d1f23a050
