Remarkably, only very few proteins are exclusively expressed in one particular cell type, the vast majority of which are expressed both in stem cells and specialized cells. Hence, the more cells possess the full toolbox of a specific protein, the more exposed the protein can be to different processes. However, in cancer, the switch of cells from a normal to a malignant state often results in acquisition of properties by single cell types that were absent in healthy tissue. This acquired feature on individual cells is called cellular heterogeneity. Cells of the human colon epithelium are as far as possible homogeneous, as the genome of each cell is identical, each expressing a specific set of genes. However, the colon epithelium of humans is not homogeneous: tumors harbor metastases of the primary tumor or otherwise are disrupted tissue. A systematic study of the molecular makeup of such cells is therefore of great interest in cancer research. Moreover, such studies are not only of interest in cancer research, but also in cancer diagnostics, as the molecular makeup of tumor cells can be used to determine the likely origin of a tumor. Cellular heterogeneity might thus also have clinical significance, but for that, it must be possible to identify cancerous cells in healthy tissue. We propose to provide a simple and efficient method for the high throughput isolation of labeled, specific single cells from heterogeneous tissue. This will be achieved by the use of an infectious retrovirus, which is based on the system of Sindbis virus, and which is engineered to target specific cell types by insertion of a receptor targeting sequence.

Q: How to wrap lines with columns in SWT?

I've been trying to wrap lines of text in my control created with the GXT grid. The approach I've tried is by adding a LineWrapPolicy to the label in the control's render method. This is not working. I have 3 rows (columns) of info. The first row of text (whose label I want to wrap) will be about 50 characters long, and the 2nd and 3rd rows of text are a variable number of lines that may be as long as 50 characters. This is the label being added to the panel in the render method of the control: `lines = new Label(c, SWT.None); lines.setText("Hello");`
